Abstract

Exergy analysis of the combined Brayton/Rankine power cycle of NTPC (National Thermal Power Corporation) Dadri India is presented. Theoretical exergy analysis is carried out for different components of Dadri combined cycle power plant which consists of a gas turbine unit, heat recovery steam generator without extra fuel consumption, and steam turbine unit. The results pinpoint that more exergy losses occurred in the gas turbine combustion chamber reaching 35% of the total exergy losses, while the exergy losses in other plant components are between 7% and 21% of the total exergy losses at 1400°C turbine inlet temperature and pressure ratio 10. This paper also considered the effect of the pressure ratio, turbine inlet temperature, pressure drop in combustion chamber, and heat recovery steam generator on the exergy losses in the plant. There are clear effects in the exergy losses when changing pressure ratio and turbine inlet temperature.

Keywords: Gas turbine cycle; steam turbine cycle; combined cycle; pressure ratio; exergy losses.

1. Introduction

Energy conservation concept (or the first law of thermodynamics) does not give the detailed analysis of the losses in power plant components. It is necessary to pinpoint the exergy losses. Exergy analysis enables one to determine the maximum work that can be expected from energy device or process; this is possible because the second law expresses the quality of energy. The purpose of this work is to analyze the performance of a combined power plant according to the second law of thermodynamics using the exergy analysis.

Most recently Mansouri et al (2012) investigated the effect of HRSG (heat recovery steam generator) pressure levels on exergy efficiency of combined cycle power plants and show that increases in the number of pressure levels of the HRSG affect the exergy losses due to heat transfer in the HRSG and the exhaust of flue gas to the stack. The different configuration of combined cycle studied by Ibrahim et al (2011) that the simple gas turbine configuration is more suitable with regards to power output, but the regenerative gas turbine configuration has higher efficiency with effect to ambient temperature. The simple gas turbine configuration has higher power output with effect to the compression ratio, while the regenerative gas turbine configuration has higher efficiency with effect to lower compression ratio; therefore the variation of total power output is insignificant at lower compression ratio.

Sanjay (2011) investigated the effect of operating parameters on the rational efficiency and exergy destruction of combined cycle and showed that higher TIT and higher compressor pressure ratio is favorable on the performance of combined cycle. The development of medium size (50-120 MW) combined cycle power plants analyzed by the Franco (2011) in which the alternative design of combined cycle power plants with a supercritical HRSG was presented without efficiency increase. Regulalagadda et al (2010) conducted a parametric study for the plant under various operating conditions, including different operating pressures, temperatures and flow rates, in order to determine the parameters that maximize plant performance. The exergy loss distribution indicates that boiler and turbine irreversibility yield the highest exergy losses in the power plant. The combined cycle system is optimized by Srinivas (2010) at a gas turbine inlet temperature of 1400°C due to the present available technology of modern gas turbine blade cooling systems and developed high performance, better conditions for compressor, HRSG sections, steam reheater and deaerator.

Aljundi (2009) presented the energy and exergy analysis of Al-Hussein power plant in Jordan where energy losses mainly occurred in the condenser and 134 MW is lost to the environment while only 13 MW was lost from the boiler system. Polyzakis et al (2008) described and compared the optimization of a combined cycle power plant of four different gas turbine cycles: simple cycle, intercooled cycle, reheated cycle and intercooled & reheated cycle. The results show that the reheated gas turbine is the most desirable overall, mainly because of its high turbine exhaust gas temperature and resulting high thermal efficiency of the bottoming steam cycle.

Koch et al (2007) studied the application of an evolutionary algorithm to the minimization of the product cost of complex combined cycle power plants. A technique to reduce the irreversibility of the steam generator of the combined cycle was introduced by Bassily (2005). The effects of varying the inlet temperature of the gas turbine (TIT) and pinch points on the performance of all cycles were presented and discussed. The results indicated that the optimized combined cycle is up to 1% higher in efficiency than the reduced-irreversibility combined-cycle, which is 2–2.5% higher in efficiency than the regularly designed combined cycle when compared for the same values of TIT and pinch points. Bejan (2002) reviewed the concept of irreversibility, entropy generation, and exergy destruction. Examples illustrate the accounting for exergy flows and accumulation in closed systems, open systems, heat transfer.
2. System Description

NTPC (National Thermal Power Corporation) was set up in the central sector in the 1975. Only PSU (Public Sector Unit) to achieve excellent rating in respect of MOU (Millions of Unit) targets signed with Government of India each year. NTPC Dadri station has also bagged ISO 14001 certification. Today NTPC contributes more than 3/5th of the total power generation in India. The schematic diagram of NTPC Dadri (Gas Unit) combined power cycle is shown in Figure 2. The gas turbine (Siemens AG, Germany, V 94.2, 131.3 MW, 2 No.) is shown as a topping plant, which forms the high temperature loop, whereas the steam plant (BHEL India, 146.5 MW, two cylinder condensing reaction, 2x22 no of stages HP) forms the low temperature loop. The connecting link between the two cycles is the heat recovery steam generator (BHEL Trichy, Vertical forced Circulation) working on the exhaust of the gas turbine. A gas turbine cycle consists of an air compressor (Siemens KWU, Type Multistage axial flow, No. of stages16), a combustion chamber (Vertical Silo Type) and a gas turbine. The turbine’s exhaust-gas goes to a heat-recovery steam generator to generate superheated steam. That steam is utilized in a standard steam power cycle, which consists of a turbine, a condenser (BHEL, Rectangular, SCD2-1200) and a pump (BHEL Hyderabad, Vertical Mixed Flow). Both the gas and steam turbines drive electric generators.

3. Thermodynamic Analysis

For thermodynamic analysis the T-s diagram (Figure 1) is concerned for the layout shown in Figure 2. The temperature of gases after leaving from gas turbine is given by

\[ T_4 = T_3 \left[ 1 - \left( \frac{r_{pg}}{r_{pg}} \right)^{\frac{1}{\gamma_s}} \right] \gamma_s \text{ where } r_{pg} = \frac{p_3}{p_4} \]  

(1)

The temperature of air after leaving the compressor

\[ T_2 = T_1 (r_{pc})^{\frac{\gamma_s - 1}{\gamma_s - 1}} \text{ where } r_{pc} = \frac{p_2}{p_1} \]  

(2)

The relation between gas turbine and compressor pressure ratio is

\[ r_{pg} = (1 - \beta_1)(1 - \beta_2)r_{pc} \]  

(3)

where \( \beta_1 \) and \( \beta_2 \) is percentage pressure drop in combustion chamber and HRSG respectively.

If the flow rate of combustion gas be 1 kg/s and that of fuel is 1 kg/s then, the flow of air = (1-f) kg/s and flow of fuel is given by

\[ f = \frac{c_p \Delta T_3 - c_p \Delta T_2}{c_v - c_p \Delta T_2} \]  

(4)

Air-fuel ratio = \( 1 - \frac{f}{f} \)  

(5)
Let the pinch point temperature difference \((T_5 - T_1)\) be \(25^0\text{C}\) then \(T_1 = (T_{Sat})_{60 \text{bar}} = 275.64^0\text{C}\) (from steam table) and \(T_5 = 275.64 + 25 = 300.64^0\text{C}\). Now from the steam table taking \(h_a\) and \(h_f\) and by energy balance mass flow rate of steam is

\[
w_s = \frac{c_{ps}(T_2 - T_5)}{(h_a - h_f)}
\]  

(7)

Let the total heat transfer in the HRSG yields the stack temperature \(T_6\). Then:

\[
T_6 = T_4 - \frac{w_s(h_a - h_f)}{c_{ps}}
\]  

(8)

For dryness fraction equating entropy \(s_a = s_{bs}\); dryness fraction at \(b\) is

\[
x_{bs} = \frac{s_a - s_f}{s_{fs}}
\]  

(9)

and enthalpy at \(b\) is

\[
h_{bs} = h_f + h_{fg} \cdot x_{bs}
\]  

(10)

The mass flow rate of gas in the cycle is

\[
m_g = \frac{m_s}{w_s}
\]  

(11)

The mass flow rate of air in compressor is

\[
m_a = (1 - f)m_g
\]  

(12)

The mass flow rate of fuel in combustion chamber is

\[
m_f = f \cdot m_g
\]  

(13)

4. Exergy Destruction in Different Components

Compressor: The exergy loss due to irreversibility in compressor is given by

\[
I_c = m_a T_o (s_2 - s_1)
\]  

(14)

where

\[
s_2 - s_1 = C_{pa} \ln \frac{T^2}{T_1} - R_o \ln \frac{P^2}{P_1} \text{ and } R_o = C_{pa} \frac{(\gamma - 1)}{\gamma}
\]

Figure 1. Temperature-Entropy diagram of Brayton/ Rankine combined cycle power plant.

Figure 2. Schematic diagram of combined cycle power plant (NTPC-Dadri, Gas Unit).
Combustor: The exergy loss due to irreversibility in combustor is given by
\[ I_{comb} = T_0 \left[ (\dot{S}_p)_3 - (\dot{S}_R)_2 \right] \] (15)

where \((\dot{S}_R)_2 = (\dot{S}_A)_2 + (\dot{S}_F)_0\) and the subscripts P, R, A and F represent products, reactants, air and fuel respectively. Therefore,
\[ I_{comb} = T_0 \left[ (\dot{S}_p)_3 - (\dot{S}_p)_0 + (\dot{S}_p)_0 - (\dot{S}_A)_0 - (\dot{S}_F)_0 + (\dot{S}_A)_0 \right] \]

Now \(\Delta S_0 = (\dot{S}_p)_0 - [(\dot{S}_p)_0 + (\dot{S}_A)_0] \) so
\[ I_{comb} = T_0 \left[ (\dot{S}_p)_3 - (\dot{S}_p)_0 + (\dot{S}_A)_0 + (\dot{S}_F)_0 - (\dot{S}_A)_0 - (\dot{S}_F)_0 + (\dot{S}_A)_0 \right] \]

\[ = T_0 \left[ m_C \ln \frac{T_3}{T_0} - m_R \ln \frac{P_3}{P_0} \right] \]

\[ = T_0 \left[ m_C \ln \frac{T_3}{T_0} - m_R \ln \frac{P_3}{P_0} + \Delta S_1 \right] \] (16)

Gas Turbine: The exergy loss due to irreversibility in gas turbine is given by
\[ I_{GT} = m_s T_0 (s_4 - s_3) \] (17)

where \((s_4 - s_3) = C_{pg} \ln \frac{T_3}{T_0} - R_a \ln \frac{P_3}{P_0}\) and
\[ R_a = C_{pg} \frac{(\gamma - 1)}{\gamma} \]

HRSG: The exergy loss due to irreversibility in heat recovery steam generator is given by
\[ I_{hrsg} = T_0 \Delta S_0 = T_0 \left[ \dot{m}_s (s_4 - s_3) + \dot{m}_a (s_6 - s_4) \right] \] (18)

where \(s_6 - s_4 = C_{pg} \ln \frac{T_0}{T_3} - R_a \ln \frac{P_0}{P_4}\)

Steam Turbine: The exergy loss due to irreversibility in steam turbine is given by
\[ I_{ST} = \dot{m}_s (s_4 - s_3) T_0 \] (19)

Since isentropic efficiency of ST is
\[ \eta_{ST} = \frac{h_a - h_b}{h_a - h_{as}} \]
(for calculating \(h_b\)) and \(h_b = h_f + x_b h_fg\)
(for calculating \(x_b\)) so \(s_b = s_f + x_b s_fg\)

Exhaust Loss: The exergy loss due to irreversibility in exhaust is given by
\[ I_{exh} = T_0 \int \frac{1 - \frac{T_0}{T}}{T_0} \dot{m}_a C_{pg} \left[ (T_0 - T_o) - T_0 \ln \frac{T_0}{T_o} \right] \]

(20)

The Carnot efficiency is
\[ \eta_{carnot} = \left( 1 - \frac{T_0}{T_3} \right) \]

The energy input to the combustion chamber is
\[ E = m_f \cdot cv \]

The exergy input to the combustion chamber is
\[ Ex = E \cdot \eta_{carnot} \]

Entropy change is
\[ \Delta S_0 = Ex - E \]

Total exergy destruction becomes
\[ I_{Total} = I_C + I_{comb} + I_{GT} + I_{hrsg} + I_{ST} + I_{exh} \] (25)

4. Results and Discussion

Based upon the methodology developed and the equations derived here, the exergy loss due to irreversibility in different components of gas/steam combined power cycle is shown here graphically. For the result we made the assumptions given in Annexure-I.

Figure 3 shows the variation of exergy loss in compressor with variation in compressor pressure ratio and turbine inlet temperature. There is clear effect of compressor pressure ratio and turbine inlet temperature on exergy loss in compressor. At low turbine inlet temperature (900°C) the exergy loss in the compressor is higher and as the turbine inlet temperature increases (1400°C), the exergy loss is minimizing rapidly. There is similar pattern in exergy loss can be seen at temperature 1000 to 1400°C but at low turbine inlet temperature, the pattern is slightly different. At any particular turbine inlet temperature as the compressor pressure ratio increases the exergy loss increases. The behavior of curve is linear from 1100 to 1400°C and increases slowly rather than at 900 to 1000°C.
Figure 4. Graph of exergy loss in combustion chamber vs $r_{pc}$ at different TIT.

Figure 4 shows the variation of exergy loss in combustion chamber with variation in compressor pressure ratio and turbine inlet temperature. At low turbine inlet temperature (900°C) the exergy loss in the combustion chamber is lower and as the turbine inlet temperature (1400°C) increases, the exergy loss is increasing rapidly. There is similar behavior in exergy loss can be seen at temperature 1000 to 1400°C but at low turbine inlet temperature, the behavior is slightly different. At any particular turbine inlet temperature as the compressor pressure ratio increases the exergy loss decreases. In combustion chamber 35% to 50% of exergy loss is calculated.

Figure 5. Graph of exergy loss in gas turbine vs $r_{pc}$ at different TIT.

Figure 5 shows the variation of exergy loss in gas turbine with variation in compressor pressure ratio and turbine inlet temperature. At low turbine inlet temperature (900°C) the exergy loss in the gas turbine is higher and as the turbine inlet temperature increases (1400°C) the exergy loss is minimizing rapidly. At any particular turbine inlet temperature as the compressor pressure ratio increases the exergy loss increases. The behavior of curve is linear from 1100°C to 1400°C and increases slowly rather than at 900 to 1000°C. In gas turbine 2-7% of exergy loss is calculated.

Figure 6. Graph of exergy loss in HRSG vs $r_{pc}$ at different TIT.

Figure 6 shows the variation of exergy loss in heat recovery steam generator with variation in compressor pressure ratio and turbine inlet temperature. At low turbine inlet temperature (900°C) the exergy loss in the HRSG is lower and as the turbine inlet temperature increases (1400°C) the exergy loss is increasing rapidly. There is similar pattern in exergy loss can be seen at temperature 1000 to 1400°C but at low turbine inlet temperature, the pattern is slightly different. At any particular turbine inlet temperature as the compressor pressure ratio increases the exergy loss decreases slowly. In HRSG 15% to 31% of exergy loss is calculated.

Figure 7. Graph of exergy loss in steam turbine vs $r_{pc}$ at different TIT.

Figure 7 shows the variation of exergy loss in steam turbine with variation in compressor pressure ratio and turbine inlet temperature. At low turbine inlet temperature (900°C) the exergy loss in the steam turbine is lower and as the turbine inlet temperature (1400°C) increases, the exergy loss is increasing rapidly. There is similar pattern in exergy loss can be seen at temperature 1000 to 1400°C but at low turbine inlet temperature, the pattern is slightly different. At any particular turbine inlet temperature as the compressor pressure ratio increases the exergy loss decreases slowly. In steam turbine 5% to 15% of exergy loss is calculated.

Figure 8 shows the variation of exergy loss in exhaust with variation in compressor pressure ratio and turbine inlet temperature. At low turbine inlet temperature (900°C) the exergy loss in the exhaust is higher and as the turbine inlet
temperature (1400° C) increases, the exergy loss is minimizing rapidly. There is similar pattern in exergy loss can be seen at temperature 1000 to 1400° C but at low turbine inlet temperature, the pattern is slightly different. At any particular turbine inlet temperature as the compressor pressure ratio increases the exergy loss increases. The behavior of curve is linear from 1100° C to 1400° C and increases slowly rather than at 900 to 1000° C. In exhaust 10-20% of exergy loss is calculated.

Figure 8. Graph of exergy loss in exhaust vs \( r_{pc} \) at different TIT.

Figure 9 shows the percentage of exergy loss in all the components. In compressor 4-8% of exergy loss is calculated.

Figure 9. Pi-chart showing percentage of exergy loss in different components (Figure is in color in the on-line version of the paper).

5. Conclusions
On the basis of above analysis the following conclusions are made by varying the pressure ratio of compressor, turbine inlet temperature.

1) The exergy analysis gives a real picture about the losses which occurred in the different plant components.

2) Fuel consumption in the combustion chamber of gas turbine is directly dependent on desired turbine inlet temperature.

3) More exergy losses occur in the combustion chamber due to combustion irreversibility and this must be reduced with the aid of advanced in the new technology as the combustion process is necessary.

4) At lower turbine inlet temperature and higher pressure ratio the exergy losses in the components compressor, gas turbine and exhaust are higher.

5) At higher turbine inlet temperature and lower pressure ratio the exergy losses in the components combustion chamber, heat recovery steam generator and steam turbine are higher.

6) There are clear effects in the exergy losses when changing pressure ratio and turbine inlet temperature.

7) The exergy balance or second law approach presented facilitates the design and optimization of complex cycles by pinpointing and quantifying the losses.

8) The optimum turbine inlet temperature and pressure ratio should be the next focus of study for minimizing the total exergy losses in all the components.
